Trevor Paglen's work warns that machines are beginning to see the world without humans, using hidden systems and algorithms to build their own vision. The article shows how AI "vision" is being trained using biased image sets that can reinforce stereotypes, rather than reflect reality. By making visible the invisible, surveillance networks, algorithmic vision, and training datasets, Paglen forces us to confront how much control we may lose over how reality is framed. His work tells us that we need to pay attention now, before these machine-made visions go unchecked.
